

Azure Session 08

Summary 09-05-2024

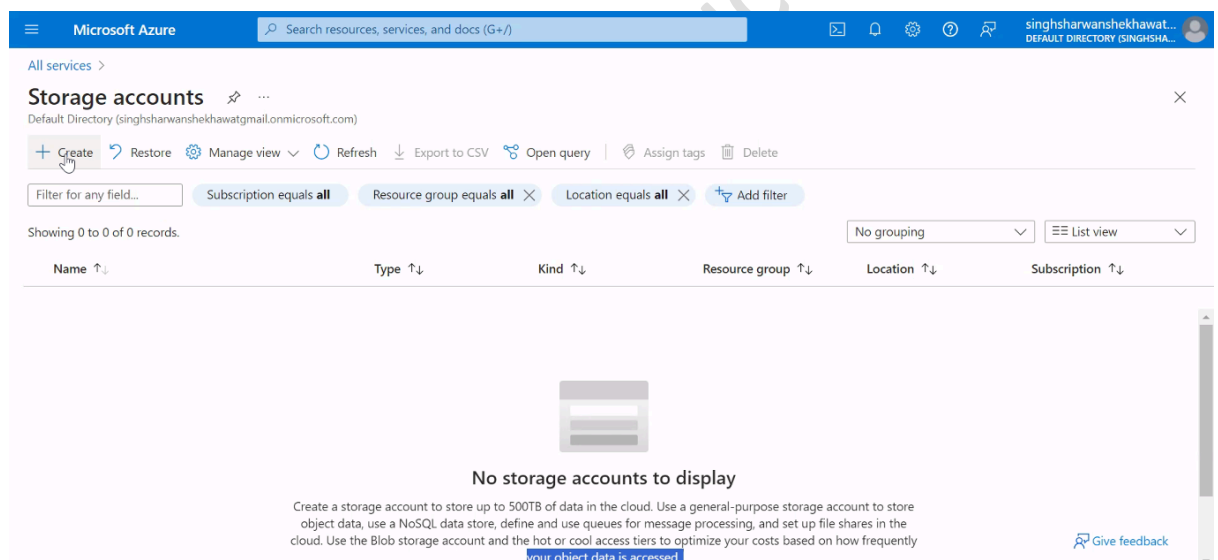

- Today we will learn about Storage as a service.
- To store any data permanently, we have to put it in a file, a file is created in a folder or the directory and to store a directory we need a storage.
- Data can be any text file, media file like audio, video, image etc.
- Storage service has mainly three use cases or types:-
 - Block storage(For storing or installing the OS,creating partitions etc)
 - Object storage(For storing objects like image, video, audio etc)
 - File System storage(NFS and NAS)

- Block storage is not a cloud managed service, we get a Raw hard disk and we have to manage or configure it. Block storage service is known as **Disks in Azure** and EBS in AWS
- For the Object storage we have the **Blob storage** service in Azure and S3 in the AWS.
 - The folder is known as container in the Blob service and Bucket in the S3
- If we want to use the storage services in Azure then we have to create a **Storage account** first.

- Creating storage account:-
 - In the storage account click on the create button.

- Like all other services we have to provide the subscription, resource group name, the storage account name and the region name.
- Make sure Storage account name is unique globally because Azure will use it to create a unique URL to access the files inside it.
- Region name is very important because according to this only we will get the storage in a particular region and all the files will be stored there.
- Costing also varies region to region so we have to select accordingly.

Create a storage account

Subscription * Free Trial

Resource group * (New) LWRGStorage123
[Create new](#)

Instance details

Storage account name * wtestblobstorage123

Region * (US) East US
[Deploy to an Azure Extended Zone](#)

Performance * Standard: Recommended for most scenarios (general-purpose v2 account)
Premium: Recommended for scenarios that require low latency.

Redundancy * Geo-redundant storage (GRS)

[Previous](#) [Next](#) [Review + create](#)

[Give feedback](#)

- If we have created the storage in Brazil and we are accessing it from India then we will face the latency issue for sure.
- Suppose in India Azure has 3 regions and whenever we upload any file, Azure creates multiple copies or replicas of it and stores them into different regions for the durability of the data. This is known as the Replication concept.
- Replication is also known as the redundancy and Azure provides different redundancy options like LRS(Locally-Redundant Storage), GRS(Geo-Redundant storage), ZRS(Zone-Redundant Storage),GZRS(Geo-Zone-Redundant storage).

Performance * Standard: Recommended for most scenarios (general-purpose v2 account)
Premium: Recommended for scenarios that require low latency.

Redundancy * Geo-redundant storage (GRS)
☐ Make read access to data available in the event of regional unavailability.

[Previous](#) [Next](#) [Review + create](#)

Locally-redundant storage (LRS):
Lowest-cost option with basic protection against server rack and drive failures. Recommended for non-critical scenarios.

Geo-redundant storage (GRS):
Intermediate option with failover capabilities in a secondary region. Recommended for backup scenarios.

Zone-redundant storage (ZRS):
Intermediate option with protection against datacenter-level failures. Recommended for high availability scenarios.

Geo-zone-redundant storage (GZRS):
Optimal data protection solution that includes the offerings of both GRS and ZRS. Recommended for critical data scenarios.

- In the LRS, Azure will create 3 replicas of data and will store it in 3 different hard disks but in the same zone.
- If any situation comes up in which the entire zone becomes down, then the LRS won't help us. Instead we have to go for the **ZRS(Zone-Redundant Storage)**.
- In the ZRS, Azure creates 6 replications of the data in which 3 will be put in one zone and the other three Copies will be put in different zones.

- If the situation is to use multiple Regions for the backup then we can go for the **GRS(Geo-Redundant storage)**, in this Azure will create the backup of the data and will store it in different regions.
- So we have to choose the redundancy according to the use case or the requirement or the strategy.
- In the Free plan we have only two performance options available.
- If we want a great performance for the storage then always try to store the data very close to the client.
- We also have different types of hard disk available according to the use case. For example, Input-Output operation speed,
- If we select the **premium performance** then we get the option for choosing the type of the hard disk also.
- For a great Input-Output or Read-Write operation we can use the **Page Blobs Store** and for low latency type storage we can use the **Block Blobs Store**.

Give feedback

- After all these things click on the next button and in the security tab allow the Rest API option.
- If we want to enable anonymous access(Anybody can access) to the Container or the Folder inside the storage then we can do that also but this is very dangerous because anyone will be able to access the files without any authentication.

The screenshot shows the 'Create a storage account' page in the Microsoft Azure portal. The 'Advanced' tab is selected, displaying security settings. The 'Require secure transfer for REST API operations' checkbox is checked. The 'Allow enabling anonymous access on individual containers' checkbox is unchecked. The 'Enable storage account key access' checkbox is checked. The 'Default to Microsoft Entra authorization in the Azure portal' checkbox is unchecked. The 'Minimum TLS version' dropdown is set to 'Version 1.2'. The 'Permitted scope for copy operations' dropdown is set to 'From any storage account'. At the bottom, there are 'Previous', 'Next', and 'Review + create' buttons. A 'Give feedback' link is also present.

- Access keys can be used to authorize access to data in your storage account via Shared Key authorization, or via SAS tokens that are signed with the shared key.
- In the networking tab enable the public access from all networks to allow access to the authorized persons.

The screenshot shows the 'Create a storage account' page in the Microsoft Azure portal, with the 'Networking' tab selected. Under 'Network connectivity', it states: 'You can connect to your storage account either publicly, via public IP addresses or service endpoints, or privately, using a private endpoint.' Under 'Network access', three radio buttons are shown: 'Enable public access from all networks' (selected), 'Enable public access from selected virtual networks and IP addresses', and 'Disable public access and use private access'. A note below the radio buttons states: 'Enabling public access from all networks might make this resource available publicly. Unless public access is required, we recommend using a more restricted access type. [Learn more](#)'. At the bottom, there are 'Previous', 'Next', and 'Review + create' buttons. A 'Give feedback' link is also present.

- Rest all the things we will keep as it is for now.
- In the Encryption tab, select the encryption type for the data.

The screenshot shows the 'Create a storage account' wizard in the Microsoft Azure portal, specifically the 'Encryption' tab. The breadcrumb navigation at the top indicates 'All services > Storage accounts >'. The wizard has several tabs: 'Basics', 'Advanced', 'Networking', 'Data protection', 'Encryption' (which is selected), 'Tags', and 'Review + create'. Under 'Encryption type *', the 'Microsoft-managed keys (MMK)' radio button is selected. Below this, the 'Enable support for customer-managed keys' section has the 'Blobs and files only' radio button selected. A warning icon and text state: 'This option cannot be changed after this storage account is created.' The 'Enable infrastructure encryption' checkbox is unchecked. At the bottom, there are three buttons: 'Previous', 'Next', and 'Review + create' (which is highlighted in blue). A 'Give feedback' link is located in the bottom right corner.
